## Bij registratierichtlijn S001 Liesbreuk (Hernia Inguinalis)

CAS-code: S631

ICD-10-codes: K40 – hernia inguinalis

Auteurs: dr Paul Kuijer, Denzel Hondebrink, dr Henk van der Molen

Juli 2019, Nederlands Centrum voor Beroepsziekten, [www.beroepsziekten.nl](http://www.beroepsziekten.nl)

Dit achtergronddocument bij de registratierichtlijn wordt beschreven aan de hand van [het 6-stappenplan voor melden van beroepsziekten](#) bij het Nederlands Centrum voor Beroepsziekten (NCvB).

### Het 6-stappenplan van het NCvB luidt:

Stap 1. Vaststellen van de aandoening/ziekte

Stap 2. Vaststellen van de relatie met werk

Stap 3. Vaststellen van de aard en het niveau van de oorzakelijke blootstelling

Stap 4. Nagaan van andere mogelijkheden en de rol van de individuele gevoeligheid

Stap 5. Concluderen en melden

Stap 6. Preventieve maatregelen en interventies inzetten en evalueren

Naast de informatie die beschreven is in de registratierichtlijn bevat dit achtergronddocument ook de referenties naar de medische literatuur die is gebruikt.

### Inleiding

Een liesbreuk of hernia inguinalis is een aandoening die bestaat uit een uitstulping van het buikvlies in de liesstreek, waardoor organen die normaal in de buikholte zitten zoals de dunne darm uit gaan puilen. Er zijn diverse soorten liesbreuken te onderscheiden, onder andere afhankelijk van de plaats ('breukpoort') waar de inhoud van de buikholte uit gaat puilen en bij volwassenen zijn dit veelal:

- de directe (mediaal, via de achterwand van het lieskanaal) liesbreuk, achter de arteria epigastria inferior langs;
- de indirecte liesbreuk (lateraal door de anulus inguinalis in het lieskanaal richting scrotum), vóór de arteria epigastria inferior langs (Friedbichler e.a. 2009).

Een liesbreuk kan pijn doen, knellen, branden of steken. Bij klachten wordt de buikwand operatief hersteld. In Nederland gebeurde dat 50.015 maal in 2015: de helft van de patiënten was in de leeftijd van 20-65 jaar namelijk 25.175 gevallen (50%) en de 1-jaars-incidentie van deze operatie is het hoogst in de leeftijdsgroep 45-65 jaar met 35% (CBS Statline 2019). Mannen hebben tijdens hun

leven 27% kans op een liesbreuk. Bij vrouwen is de kans een stuk lager: 3% (Zorgkaart Nederland 2015).

### **Stap 1. Vaststelling van de aandoening**

De diagnose liesbreuk wordt bij volwassenen ouder dan 18 jaar gesteld op basis van anamnese en lichamelijk onderzoek (Nederlandse Vereniging voor Heelkunde 2003):

- Bij de anamnese wordt aandacht besteed aan: zwelling lies, rechts/links, aard klachten (pijn), duur klachten, contralaterale lies zwelling, beklemmingverschijnselen, reponibel, eerdere liesoperaties;
- Bij lichamelijk onderzoek wordt aandacht besteed aan: zwelling lies (boven het ligament van Poupart), operatielitteken liesregio, contralaterale lies, beklemmingsverschijnselen, reponibel, testes, NB Het onderscheid lateraal/mediaal is onbetrouwbaar op basis van lichamelijk onderzoek;
- Differentiaaldiagnoses zijn femoraalbreuk, lymfklierzwelling, aneurysma, varix vena saphena magna, wekedelentumor, abces, en corpus alienum (gossipyboma);
- Aanvullende diagnostiek zoals herniografie, MRI, echo of laparoscopie is zelden nodig.

### **Stap 2. Vaststellen van de relatie met werk**

De drie criteria die experts hanteren om de relatie met werk vast te stellen van een ziekte of aandoening zijn de grootte van de bewezen risicofactoren uit de medische literatuur, een tijdsrelatie en de biologische plausibiliteit (Verbeek 2012). Voor een populatie werknemers met een bepaalde blootstelling of een bepaalde beroepsgroep wordt een ziekte of aandoening veelal aangemerkt als beroepsziekte als de etiologische fractie door risico's in het werk  $\geq 50\%$  is. Het relatief risico is dan twee of groter. Een etiologische fractie van 50% impliceert dat onder de zieke blootgestelde personen 50% van de ziekten te wijten is aan de blootstelling. Op individueel niveau dient de bedrijfsarts te bepalen of liesbreuk bij de werknemer in overwegende mate wordt veroorzaakt door het werk op basis van op populatieniveau verkregen evidence-based risicofactoren. Bij het vaststellen of er een oorzakelijk verband met werk zou kunnen zijn voor een individuele werknemer is zoals gezegd ook de tijdsrelatie van belang (klachten ontstaan nadat met het huidige werk is begonnen, verergering van klachten door specifieke taken of na drukke perioden, klachten zijn minder na vrije dagen of vakantie of de invoering van preventieve maatregelen) en of de risicofactor in werk ook in lijn is met het veronderstelde pathofysiologische mechanisme voor de aandoening of ziekte, denk bijvoorbeeld aan een voldoende latentieperiode of blootstellingsduur of 'overbelasting van bepaalde structuren zonder voldoende herstel'.

### **Stap 3. Vaststellen van aard en niveau van de oorzakelijke blootstelling**

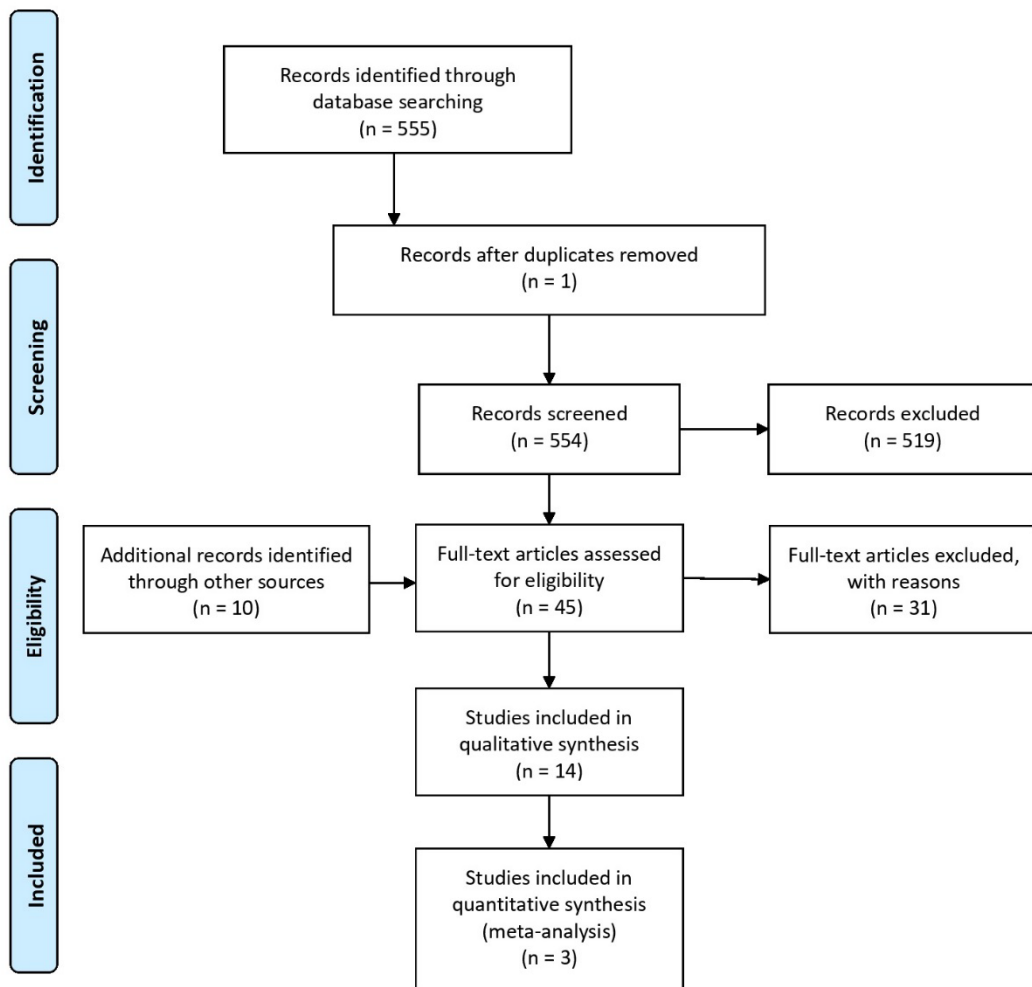

De werkgerelateerde risicofactoren zijn gebaseerd op een systematische literatuurstudie uitgevoerd in PubMed tot en met 14 mei 2018 (Hondebrink 2018). De vraagstelling was 'Wat zijn werkgerelateerde risicofactoren voor een liesbreuk bij werkenden?'. De zoekstrategie staat in tabel 1. Twee auteurs (DH en PK) beoordeelden onafhankelijk van elkaar alle artikelen op basis van de titel

en samenvattingen met behulp van de website 'rayyan.qcri.org'. Om aan de inclusiecriteria te voldoen, moesten de studies rapporteren over werkgerelateerde risicofactoren en over door een arts vastgestelde liesbreuken bij werkende patiënten. Wanneer consensus was bereikt, werden de volledige artikelen gelezen en opnieuw onafhankelijk beoordeeld aan de hand van de genoemde inclusiecriteria.

**Tabel 1. Zoekstrategie PubMed**

Kernbegrip	Zoektermen PubMed
Werkende	((adult[mesh]) OR (adult[tiab]) OR (middle aged[mesh]) OR (middle aged[tiab]))
Liesbreuk	((inguinal hernia[mesh]) OR (inguinal hernia[tiab]))
Risicofactoren in werk	((occupational disease*[mesh]) OR (occupational disease*[tiab]) OR (risk factor*[mesh]) OR (risk factor*[tiab]) OR (work-related[mesh]) OR (work-related[tiab]) OR (etiology[mesh]) OR (etiology[tiab]))

Na consensus werd de literatuurlijst van de geïncludeerde artikelen ook gecontroleerd op mogelijk relevante studies. Daarnaast is ook gekeken of de aanvulling op de literatuurstudie van Svendsen e.a. (2013) uit het proefschrift van Vad (2018) met een zelfde vraagstelling over de periode 3 november 2011 tot en met 1 mei 2018 nog extra artikelen opleverde. Deze zoekstrategie resulteerde uiteindelijk in 14 artikelen over een relatie met werk (Figuur 1). De drie studies die konden worden gebruikt in een meta-analyse en zijn door twee auteurs (DH, PK) op kwaliteit beoordeeld met het beoordelingsinstrument van Van der Molen e.a. (2012) (Bijlage I). Dit is ook gebeurd voor de twee studies die rapporteerden over de blootstelling in termen van werkgerelateerde activiteiten (Tabel 2). Bij meer dan 11 punten scoorden de studies een laag risico op vertekening (bias). De relevante kenmerken uit de 14 studies zijn weergegeven in bijlage II (Hondebrink 2018). Tot slot is ook GRADE toegepast om de mate van zekerheid over de uitkomst te graderen in termen van zeer laag, laag, redelijk en hoog (Bijlage III, <http://dutchgradenetwork.org>). Deze beoordeling wordt vertaald in respectievelijk 'weinig, beperkt, redelijk of veel vertrouwen in de schatting van het gunstige of ongunstige effect van de risicofactor op het krijgen van een liesbreuk.'

Figuur 1. Stroomdiagram van de inclusie van de artikelen

De 14 studies zijn verdeeld naar de manier waarop deze de werkgerelateerde fysieke risicofactoren beschreven namelijk aan de hand van de economische sector of beroep, de mate van fysieke belasting of in termen van de risicovolle werkgerelateerde activiteiten zoals staan, lopen en tillen.

Tabel 2. De kwaliteitsbeoordeling van de studies uit de meta-analyse en de werkgerelateerde activiteiten. Alle vijf studies hadden een laag risico op vertekening

## Economische sector of beroep

Een cross-sectionele studie (Kang 1999) noemde onder andere de volgende economische sectoren en beroepen met een verhoogde kans op het hebben van een liesbreuk in vergelijking met de totale mannelijke populatie werkenden: bouw, productie, groothandel, (hand)arbeiders, machinebedieners, assemblagepersoneel, (onderhoud)reparateurs, en transport- en logistiekmedewerkers.

## Fysieke belasting

Twee case-reports, vijf case-control studies en drie prospectieve cohort studies beschreven de risicofactor fysieke belasting (Hondebrink 2018). Twee case-control studies bij mannen en vrouwen (Flich e.a. 1992, Carbonell e.a. 1993) en een prospectieve cohortstudie bij mannen (Ruhl & Everhart 2006), allen van hoge kwaliteit, konden worden gecombineerd in een meta-analyse en toonden aan dat zware fysieke belasting in werk de kans op een liesbreuk verhoogt met een gepoolde OR van 2,30 (1,56-3,40) (Figuur 2). Zware fysieke belasting was gebaseerd op een zelf-rapportage over de mate van inspanning tijdens het werk gecategoriseerd in vier categorieën (geen, licht, gemiddeld, zwaar, Flich e.a. 1992), een zwaartescore van 1 tot en met 10 berekend op basis van een zelf-rapportage over onder andere het aantal dagen per week dat zwaar werk wordt verricht, het gewicht van de eventueel te tillen objecten en of het werk staan of zittend werd verricht (Carbonell e.a. 1993), en een zelf-rapportage over niet-recreatieve activiteiten in drie categorieën laag actief, matig actief, en hoog actief (Ruhl & Everhart 2006). Bij het beoordelen van de mate van zekerheid met GRADE is de conclusie dat 'er beperkt vertrouwen is in de schatting van het ongunstige effect van zware fysieke belasting op het krijgen van een liesbreuk.' (Bijlage III, pagina 38).

Figuur 2. Forest plot met het gewogen risico van fysiek zwaar werk voor een liesbreuk gebaseerd op drie studies van hoge kwaliteit

## Werkgerelateerde activiteiten

Door Sanjay & Woodward (2007) en Vad e.a. (2012, 2017) zijn de werkgerelateerde activiteiten staan/lopen en tillen onderzocht. Door het ontbreken van een controlegroep, konden alleen de studies van Vad (2012, 2017) worden gebruikt. Deze beschrijven het risico op een liesbreuk bij mannen. Zij vonden in de eerste plaats dat deze werkgerelateerde activiteiten alleen een risicofactor zijn voor een laterale (indirecte) liesbreuk en niet voor een mediale (directe). Dit bleek vooral te gelden voor werk dat gekenmerkt werd door meer dan zes uur per dag staan of lopen (HR =1,45 95% Betrouwbaarheidsinterval 1,12-1,88, gecorrigeerd voor onder andere leeftijd, BMI, lichamelijke activiteit in de vrije tijd, en roken) en voor tillen van meer dan 4000 kg per dag (OR=1,32 95% Betrouwbaarheidsinterval 1,27-1,38, gecorrigeerd voor leeftijd, sociaal economische positie en regio in het land) (Bijlage III, pagina 38). Bij het beoordelen van de mate van zekerheid met GRADE is de conclusie dat 'er matig vertrouwen is in de schatting van het ongunstige effect van meer dan zes uur per dag staan of lopen en voor tillen van meer dan 4000 kg per dag op het krijgen van een liesbreuk' (Bijlage III, pagina 38).

### **Stap 4. Nagaan van andere mogelijkheden en de rol van de individuele gevoeligheid**

Persoonsgebonden factoren die het risico op een liesbreuk vergroten bij werkenden zijn oudere leeftijd (>40 jaar) (Ruhl & Everhart 2007, Vad e.a. 2012, 2017) en man zijn (Ruhl & Everhart 2007, Vad e.a. 2012, 2017). Het hebben overgewicht en/of obesitas lijkt het risico te verlagen (Ruhl & Everhart 2007, Vad e.a. 2017). Roken en lichamelijke activiteit in de vrije tijd resulteerden niet in een grotere of kleine kans op een liesbreuk (Vad e.a. 2017).

### **Stap 5. Concluderen en melden**

Er is bewijs voor een liesbreuk als beroepsziekte wanneer deze aanwezig is bij een mannelijke of vrouwelijke werkende die enige jaren zwaar lichamelijk werk heeft verricht. De mate van zekerheid is redelijk tot hoog als het ook een mannelijk werkende is, die gediagnosticeerd is met een laterale (indirecte) liesbreuk en wiens werk bestaat uit meer dan 6 uur per dag staan of lopen en/of meer dan 4000 kg tillen.

### **Stap 6. Preventieve maatregelen en interventies inzetten en evalueren**

Maximaal 31% van de liesbreuken treedt theoretisch niet op als de werkbelasting wordt verlaagd naar minder dan 4 uur per dag staan of lopen berekende Vad (2017). Zij stelt dat wanneer de tijdsduur staan of lopen verminderd kan worden tot maximaal 4 uur het risico op een werkgerelateerde liesbreuk niet meer verhoogd aanwezig is. Ook het verminderen van de tilbelasting per dag verkleint theoretisch dit risico, bij voorkeur tot maximaal 1000 kg (Vad 2018). Specifieke studies naar het effect van preventieve maatregelen in werk op het krijgen van een liesbreuk zijn niet gevonden. De oplossing dient dus gevonden te worden in effectieve oplossingen om langdurig staan en/of zwaar tillen te verminderen. Effectieve oplossingen voor tillen zijn beschreven in de multidisciplinaire richtlijn 'Vermindering van tilbelasting om rugklachten te voorkómen' (Kuijer e.a. 2014): <https://aoemj.biomedcentral.com/articles/10.1186/2052-4374-26-16>  
Voor langdurig staan bestaat op dit moment geen vergelijkbare richtlijn.

Voorbeelden van oplossingen uit de praktijk die effectief kunnen zijn, zijn beschreven in de arbocatalogi voor diverse sectoren en branches: <https://www.arboportaal.nl/externe-bronnen/arbocatalogi>.

### Bijlage I Beoordelingsformulier kwaliteit van artikelen (Van der Molen e.a. 2017)

ID:

Study population		
1 Study groups (exposed and unexposed) are clearly defined	Positive if at least 2 of the following 3 items in both groups were reported at baseline: age, gender; sport/leisure time exposure	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
2 Participation $\geq 70\%$	Positive if the participation of both the exposed and unexposed groups was $\geq 70\%$	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
3 Number of cases $\geq 50$	Positive if the total number of cases was $\geq 50$	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
Assessment of exposure		
4 Exposure definition	Positive if the exposure was clearly defined Definition included at least two of the three	<input type="checkbox"/> Positive

	aspects(duration, frequency, intensity) for instance cumulative exposure over the subject's working life: duration X intensity	<input type="checkbox"/> Negative <input type="checkbox"/> Unclear
5 Assessment of exposure	<p>Positive if the assessment of exposure was described</p> <p>Exposure (risk factors, independent variables) were measured using known "gold standard" (define specific for the exposure) like direct observations, instrumented measurements for WBV or goniometers</p> <p>Unclear, negative The authors did not validate the methods to measure exposure (risk factors, independent variables)</p>	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
6 Blind for outcome status	Positive if the exposure was assessed by an independent person and not based on self-report	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
<b>Assessment of outcome (specific disorder)</b>		
7 Outcome definition	<p>Positive if the outcome was clearly defined</p> <p>Case definition provided</p>	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
8 Assessment method	<p>Positive if the method of assessment was suitable</p> <p>Clinically defined disorder</p>	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear

9 Blind for exposure status	Positive if the outcome was measured without knowledge of the exposure status by an independent person, thus not based on self-reported symptoms	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
<b>Study Design</b>		
10 Prospective design or a retrospective cohort	Positive if the study design was prospective or a retrospective cohort	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear <input type="checkbox"/> Not applicable
11 Inclusion and exclusion criteria	Positive if inclusion and exclusion criteria were described	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
12 Follow-up period $\geq 1$ year	Positive if the follow-up period was $\geq 1$ year	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
13 Information on study completers versus withdrawals	Positive if demographic information was given for completers and withdrawals	<input type="checkbox"/> Positive <input type="checkbox"/> Negative

		<input type="checkbox"/> Unclear
<b>Analysis and data presentation</b>		
14 Data presentation	Positive if risk estimates were presented or when raw data were given that allow the calculation of risk estimates, such as: odds or prevalence ratios or relative risks	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
15 Consideration of confounders	Positive if the confounders that were considered were described	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear
16 Control for confounding	Positive if the method used to control for confounding was described.	<input type="checkbox"/> Positive <input type="checkbox"/> Negative <input type="checkbox"/> Unclear

		The effort score ranged from 1 to 10, after logarithmically converting the multiplied value of each variable.		
Dickerman, <i>et al.</i> 2004 Case-report study (4/16)	N = 1, a 42-year old male powerlifter who was seen for complaints of excessive oesophageal reflux, an umbilical hernia and bilateral inguinal hernias.	Wearing a powerlifting belt, since the inguinal hernias occurred after the umbilical hernia while the patient was wearing a belt.	N/A	According to the study, there is no doubt the subject's competitive powerlifting career predisposed him to hernia formation. Even though no reports on an increased incidence of inguinal or umbilical hernias developing in power athletes, they previously established the increased incidence of hiatal hernias in young powerlifters and thus propose that this case of multiple hernias is likely the result of a pressure-overload syndrome that can occur in competitive powerlifters.
Flich, et al. 1992 Case-control study (13/16)	The 128 cases were all patients with inguinal hernias treated in 1986 in the hospital (the General Hospital of Valencia). All were in-patients for surgery.  The 174 controls were selected from the same geographic area. They were randomly selected from the total population	Physical activity, including intensity and length of time in activity, was split into four categories. <p>Pathak and Poston</p> <p>2006</p> <p>Prospective cohort study (7/16)</p>	<p>Questionnaires were issued to a consecutive cohort of new patients presenting with an abdominal wall hernia. Data were collected from a single cohort study of patients presenting to a general surgical clinic at an urban general hospital over a 6-month period (January 2003 to June 2003).</p>	<p>Single strenuous or traumatic event.</p>	<p>All cases were clinically diagnosed. Single strenuous or traumatic events were compared to non-strenuous events.</p>	<p>From 133 cases 119 (89%) hernias had been gradual or insidious in onset. There were 14 patients (11%) with a convincing history correlating the symptoms to a single strenuous event. 5 patients of those 14 had no risk factors. One of those 14 stated that they had a strenuous job which involved repetitive heavy lifting or straining. Three patients stated that they believed that their hernias had developed due to strenuous exercise and stretching. Two patients claimed that coughing precipitated their hernia, and two said that their hernia came on suddenly but could not recall what they were doing at the time. The remainder believed that the aetiology of their hernias was related to a strenuous event but were unable to identify specifically the causal act. None of these 6 undertook a job that included strenuous physical labouring.</p>

Single strenuous or traumatic events</p>	<p>From 129 cases 120 (93%) hernias had been gradual or insidious in onset. In 9 patients (7%) there was a convincing history suggesting an association between</p>

<p>Prospective cohort study (7/16)</p>	<p>N = 129 patients, age 20-89.</p> <ul style="list-style-type: none"> <li>• 122♂</li> <li>• 7♀</li> </ul>		<p>were compared to non-strenuous events.</p>	<p>a particular muscle strain, groin pain and the discovery of a groin swelling.</p> <p>None of these had previously had a hernia repair or appendectomy. Four of the nine patients had a strenuous job, of whom three claimed that the incident had occurred at work. None had any associated medical problems such as chronic chest disease or bladder outflow obstruction. In one patient the diagnosis was made by a doctor within a few days, the remainder being diagnosed between 1 week and 4 years later, median 3.5 weeks. At operation five of these patients had a direct hernia, three had indirect sacs, and one has not had surgery. One patient described a fall which seemed to precipitate the hernia, while the remainder described lifting strains either at home or work.</p>
